Foundation Design and Construction

2009 Construction Training

Western Federal Lands Highway Division

Brian Collins, P.E.

Geotechnical Engineer

Session Outline

- Foundation Selection
 - Surface and subsurface conditions
 - Pros and cons
- Design
- Construction
- Case History

Foundation Selection

Site Surface and Subsurface Conditions

- Topography
- Vegetation
- Utilities
- Rivers
- Railroad tracks
- Roads/highways
- Landslides, debris flows, slumps, creeps, etc.
- Subsurface soil types
- Depth to bedrock or hard stratum
- Location of water table
- Wetlands
- Historical sites

Subsurface Conditions

- Soil profile
- Water table
- Depth to bedrock/hard stratum
- Compressible soils drag loads
- Site seismicity
- Nearby faults

Spread Footings

(within 10 feet of existing grade)

• Pros:

- Usually most cost effective for shallow depths
- Easy to construct
- No specialty contractor required
- Subgrade can be easily inspected before pouring concrete

• Cons:

- Require large excavation size increases with depth
- Constructability below water table and in water ways.
- Susceptible to scour

Driven Piles

(when spread footings aren't feasible)

• Pros

- Most contractors can perform the work
- Transmit loads deep
- Inexpensive to dynamic test (PDA and CAPWAP)
- Closed-end pipe & monotube piles can be inspected for damage after driving

Cons

- Potential to buckle during deep scour event
- May not be feasible to drive below deep scour elevations
- Difficult to install in some conditions may be damaged in cobbles and boulders
- Design is difficult when there is no bedrock or hard stratum floating piles – potential for costly change orders
- H-piles cannot be inspected after driving

Hmmm...

D'oh!

Drilled Shafts

(when spread footings aren't feasible)

Pros

- Transmit loads deep
- High axial and lateral capacities
- Minimal footprint can be constructed in river without cofferdam

• Cons

- Relatively expensive
- Requires specialty contractor
- Costly to verify loads
- Can be difficult to install in bouldery deposits

Piles v. Shafts

(when spread footings aren't feasible)

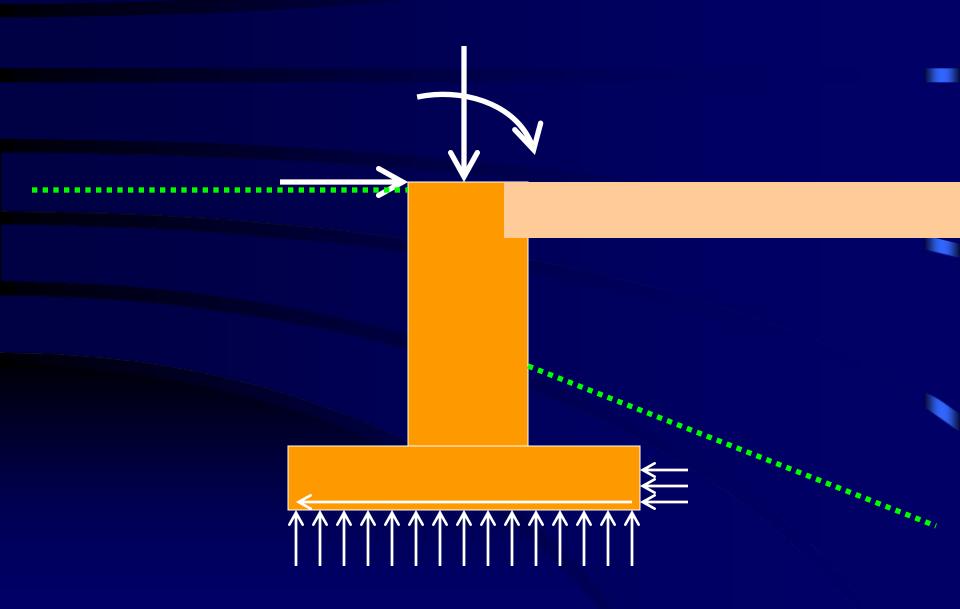

- Piles
 - Soft stratum overlying bedrock
 - Scour is not significant
 - Lateral loads are relatively small
- Drilled shafts
 - Axial and lateral loads are significant
 - Deep scour

Design

Design – Sizing Foundations

- Axial Capacity
- Lateral Capacity
- Settlement

Spread Footings

Spread Footings

$$q_u = cN_cF_{cs}F_{cd}F_{ci} + qN_qF_{qs}F_{qd}F_{qi} + 1/2\gamma BN_\gamma F_{\gamma s}F_{\gamma d}F_{\gamma i}$$

c = cohesion

q = effective stress at bottom of footing elevation

 γ = unit weight of soil

B = width of footing

 F_{cs} , F_{gs} , F_{vs} = shape factors

 F_{cd} , F_{qd} , $F_{\gamma d}$ = depth factors

 F_{ci} , F_{qi} , $F_{\gamma i}$ = load inclination factors

 N_c , N_q , N_{γ} = bearing capacity factors

Driven Piles

Driven Piles and Drilled Shafts

$$Q_{\rm u} = (\pi D L)q_{\rm s} + (\pi D^2/4)q_{\rm p}$$

D = diameter

L = length

 $q_s = skin resistance$

 $q_p = point resistance$

Spread Footings

- Keep water out of excavation at all times
- Have a Geotech look at the subgrade conditions before pouring concrete

Driven Piles

ICE I -80

I-80V2		
Ram Weight	17700	lbs
Maximum Geometric Stroke	13.5	ft
Energy @ Max Stroke	238950	ft-lbs
Rated Continuous Stroke	12	ft
Energy @ Rated Stroke	212400	ft-lbs
Blow Rate	33-53	bpm
Weight w/ Box-lead Guides	41920	lbs
Typical Helmet Weight	5200	lbs
Typical Operating Weight	47120	lbs

Driven Piles

- Keep driving logs for <u>all</u> piles
- Understand the basis for the design required minimum tip elevation and required ultimate capacity
- Never use ENR formula

Drive to specified tip elevation, minimum capacity, or both?

Pile Specifications – Equipment Submittal

- Equipment Submittal includes wave equation analysis - forward to Geotech for review
- Wave equation analysis must show that the proposed hammer system can drive the piles to the required ultimate capacity at between 3 and 10 blows/inch

Pile Specifications – Driven Pile Capacity

- Test piles
- Wave equation GRL WEAP
- Dynamic formula

$$R_u = 1.6\sqrt{eE} \log_{10}(10N) - 100$$

- Load Tests
 - PDA Pile Dynamic Analyzer & CAPWAP CAse Pile Wave Analysis Program
 - Static Load Test

Drilled Shafts

Drilled Shafts

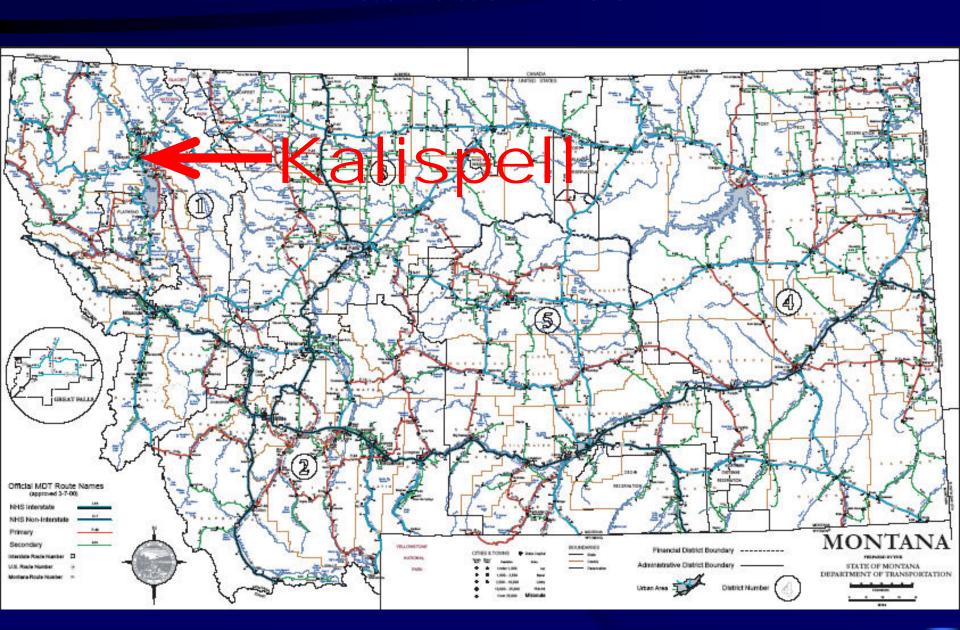

- Keep a log of the excavation Geotech
- Clean out shaft after completion
- Installation methods
 - Dry Method (above water table and cohesive soils)
 - Wet Method (below water table and cohesionless soils)
 - Slurry
 - Casing

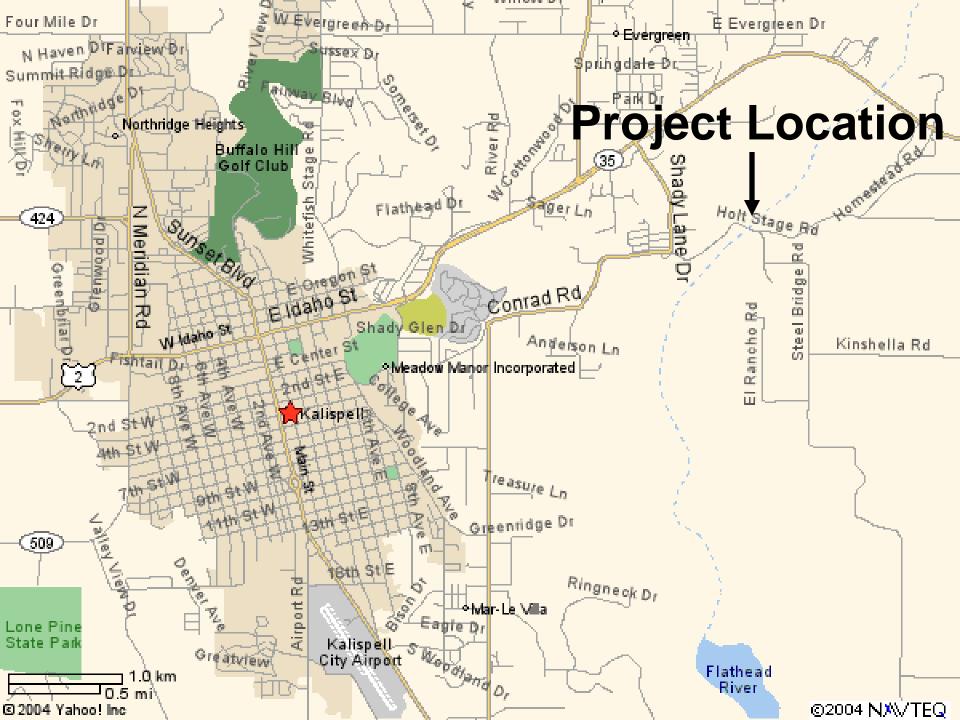

Drilled Shaft Specifications

- Installation Plan Submittal forward to Geotech for review
- Installation method wet or dry
- Inspect shaft test hole, SPT, or visual
- Concrete pour
 - Maintain 5 ft head of concrete above water when using casing
 - Free fall pour only allowed in dry holes
 - Use tremie or pump in wet holes keep end of tremie/hose below level of concrete
- Perform CSL (cross-hole sonic log) testing

Case History

Flathead River

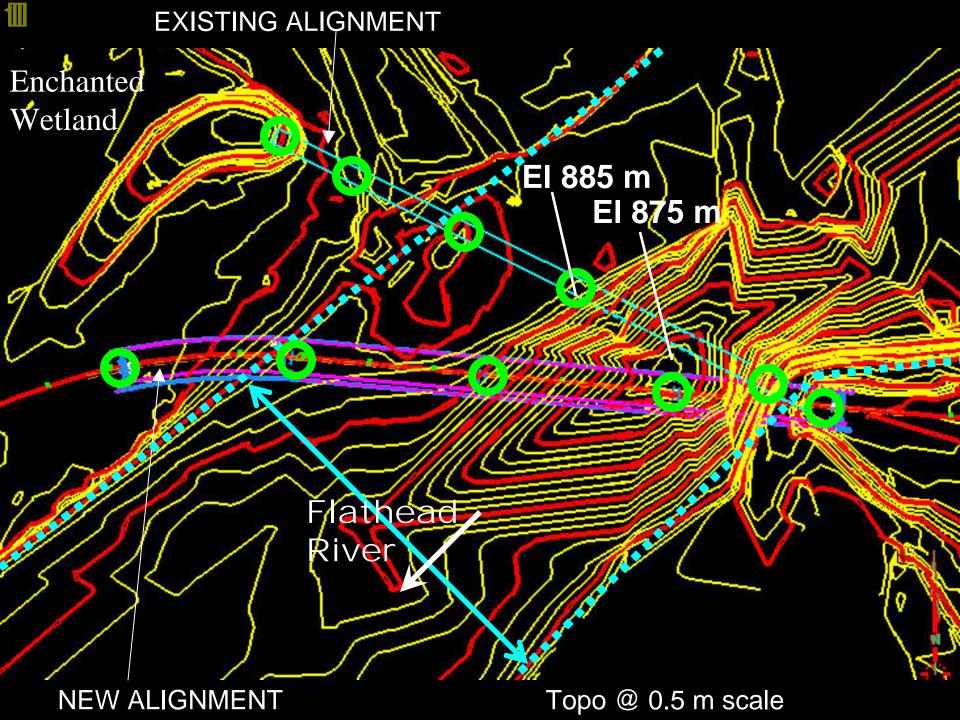

The Old
Bridge Had
Some Issues

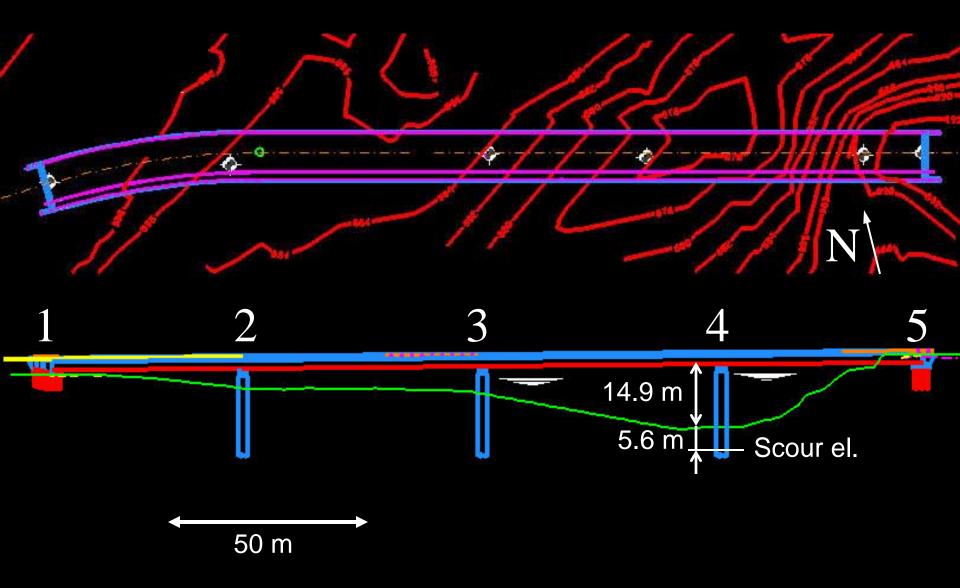

Existing Bridge

- Constructed in 1894
- Total length = 184 m (600 ft)
- Five timber approach spans
- Three steel through-truss main spans
- 2 @ 43 m (140 ft)
 - 1 @ 77 m (250 ft)
- Expansion bearings no longer function
- Severely deteriorated timber deck and abutments
- Closed for safety reasons in June 2005

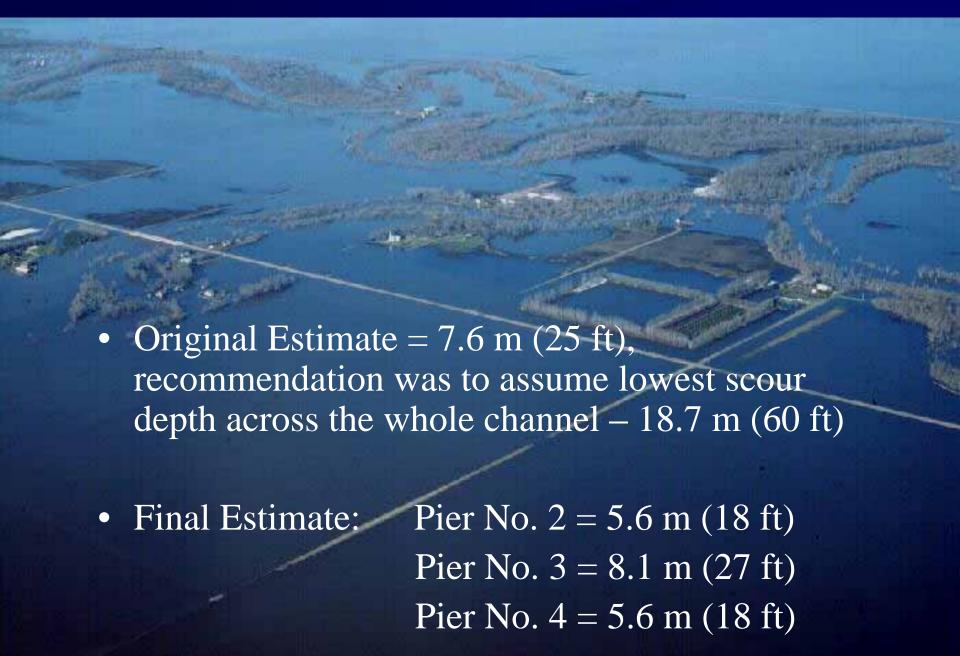

Plan & Profile

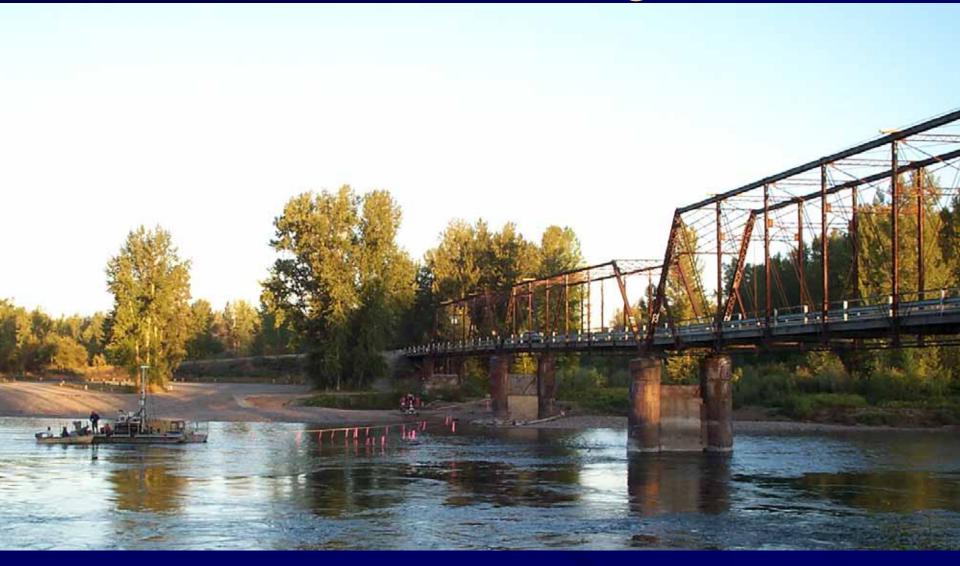

Design Loads for Drilled Shafts

- Axial Load: 10,695 kN (1200 ton)
- Lateral Loads:
 - Pier No. 2 = 1711 kN (192 ton)
 - Pier No. 3 = 1744 kN (196 ton)
 - Pier No. 4 = 1802 kN (203 ton)

Scour

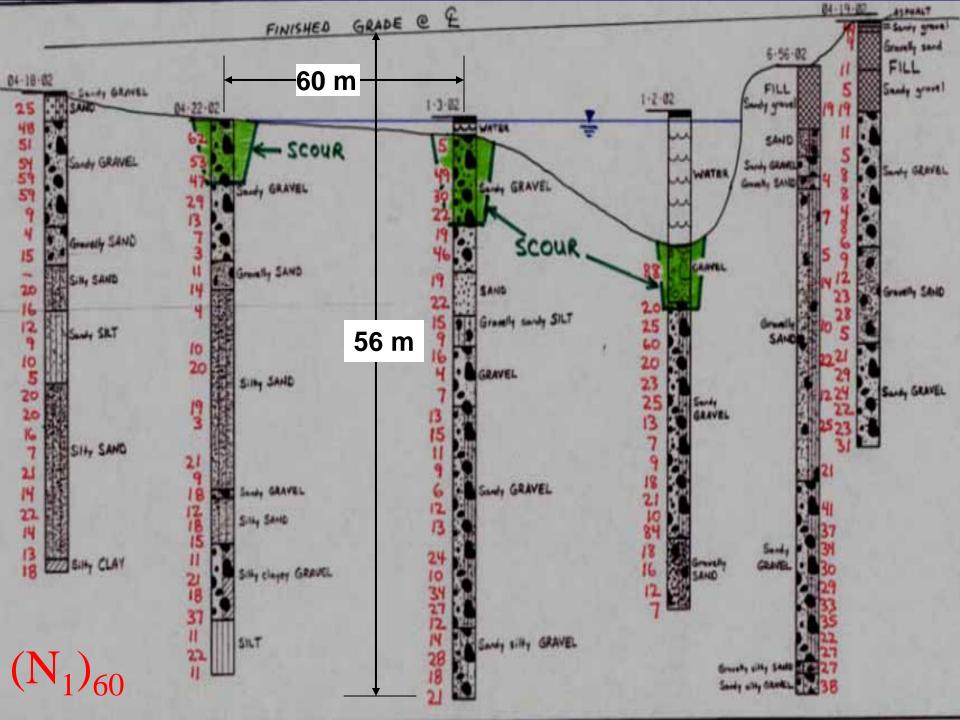

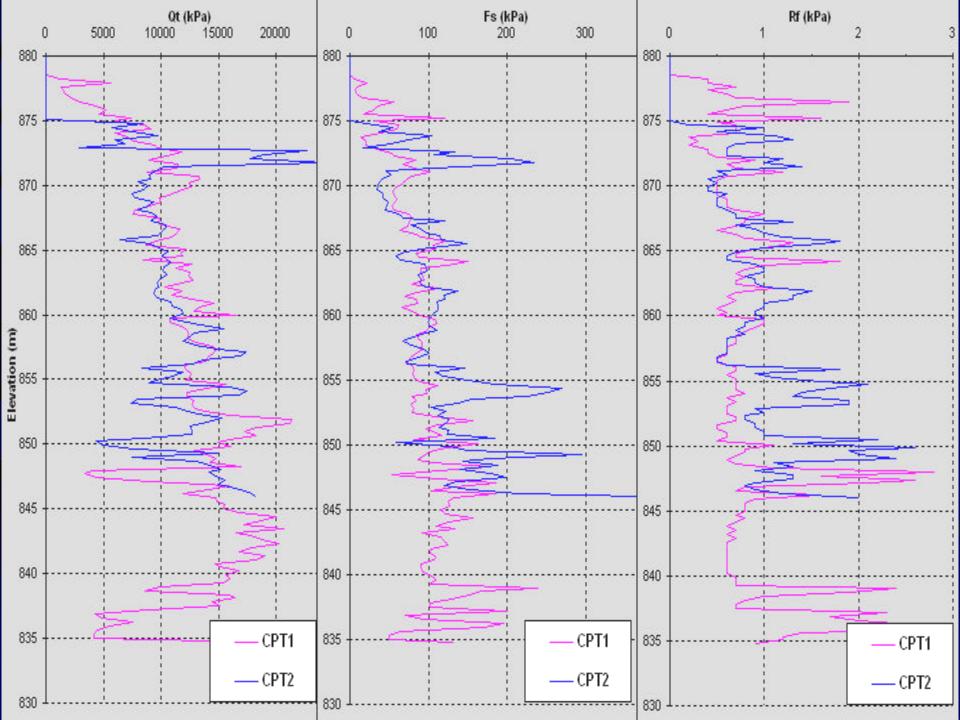

Subsurface Investigation

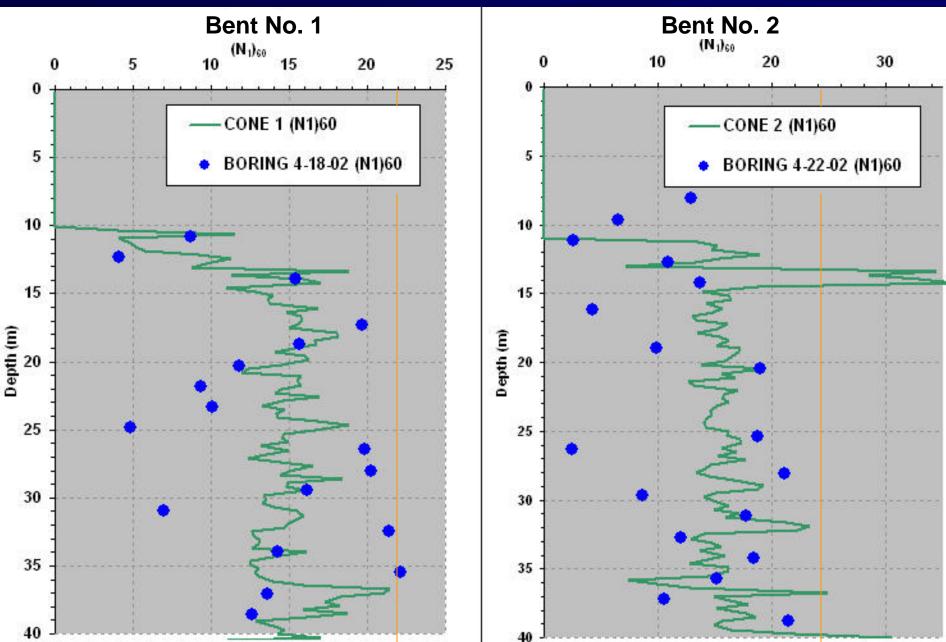

Area Geology

- Alluvium consisting mostly of valley fill (Holocene deposits)
 - Clay, silt, sand, gravel and cobbles, occasional boulders
- Depth to bedrock is about 730 m (2400 ft) (Smith, 2004)

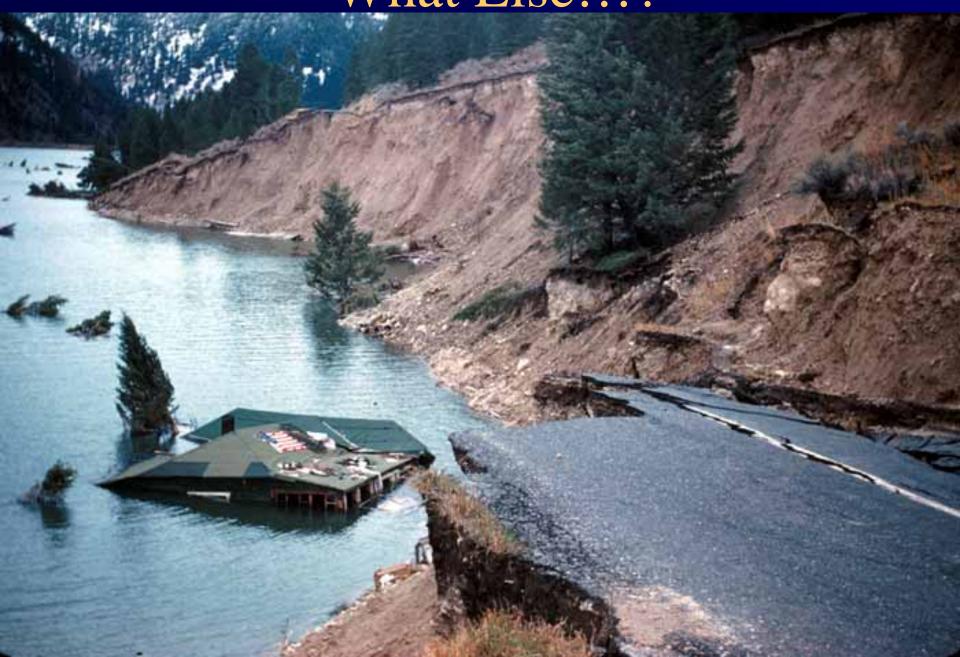

Comparison between CPT and SPT – $(N_1)_{60}$

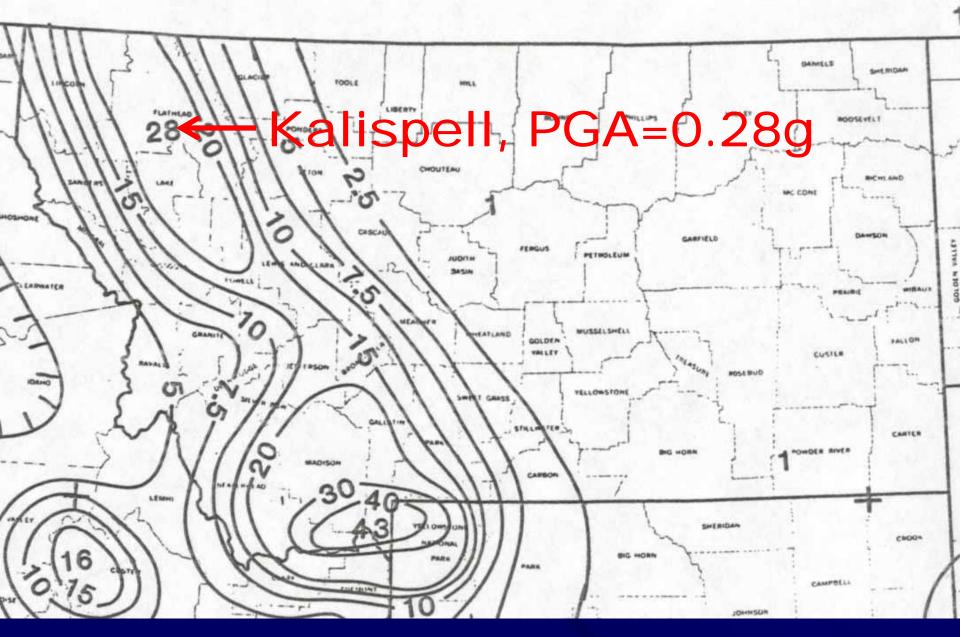

Summary of Site Investigation

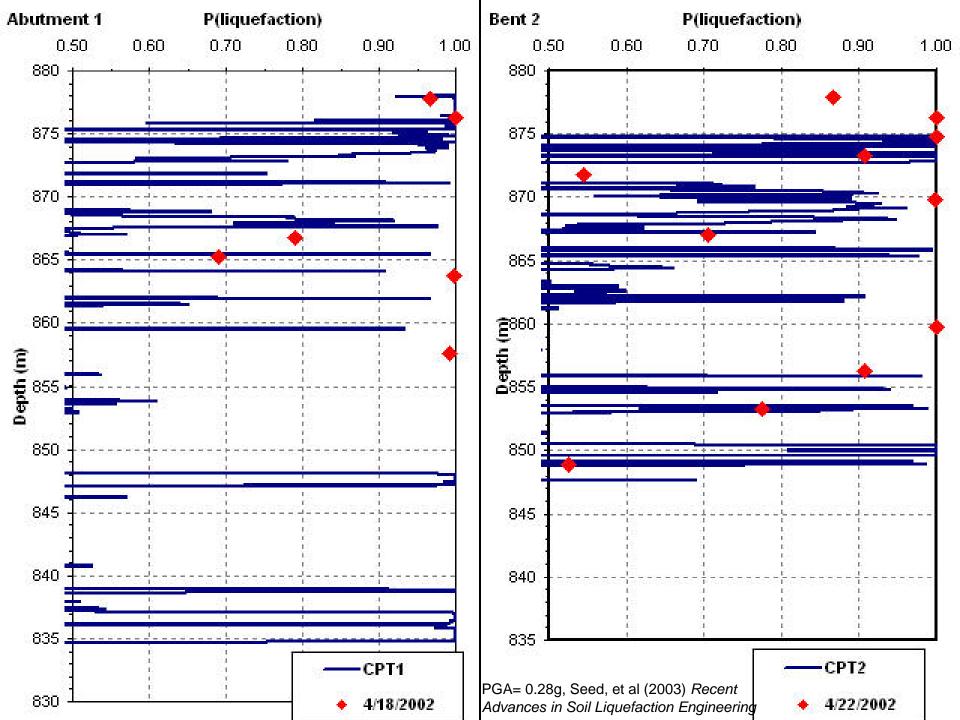

- Typical alluvial environment variable stratigraphy
- Deep cohesionless deposits with no dense bearing stratum encountered
- Decent correlation between SPT and CPTu
- Fines are nonplastic

What Else...?

AASHTO Map of Horizontal Acceleration

Design Considerations

- Bridge alignment and layout
- Lack of dense/hard bearing stratum
- Potential for liquefaction
 - Loss of pile capacity
 - Drag loads
 - Slope stability
- Piers (especially Pier No. 4)
 - Deep water
 - Significant scour
 - Large axial and lateral loads

Design Considerations, cont'd

- End bents driven piles
- Constructability of Pier No. 4
 - Deep water with fast current
 - Will installation and removal of temporary casing be feasible? What will capacity be with full length permanent casing?
 - Contractor qualifications
- Cost \$,\$\$\$,\$\$\$

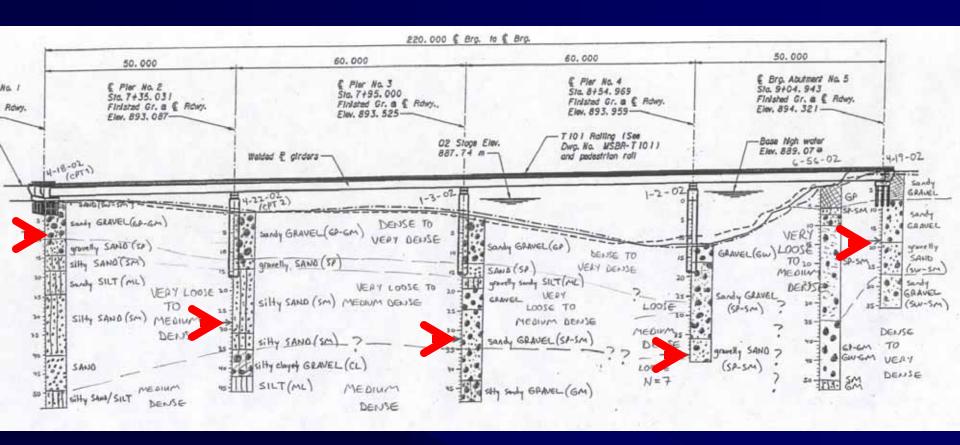

Design Recommendations

- Change alignment and/or bridge layout—
- Mitigate scour—
- Perform ground improvement around *each* of the foundation elements
- 508 mm (20") pipe piles at abutments
- Build some really big drilled shafts
- Use contractor having experience installing large diameter drilled shafts below a water surface
- \$ Increase cost estimate \$

Design Recommendations

	Pier No. 2	Pier No. 3	Pier No. 4
Diameter, m	3.05	3.05	3.51
(ft)	(10)	(10)	(11.5)
Total Length, m	30.7	35.5	43.0
(ft)	(100)	(116)	(141)
Length Below	22.4	22.5	22.5
Scour El., m (ft)	(73)	(75)	(75)
